

Chemical class frequency by position — the 193 non-substrate controls (background panel) (positions 4–12)

same matrix, same 0–45% scale, for the controls

Colour and cell text are the same number: the percentage of the $n = 193$ non-substrate controls carrying the same motif with that class at that position (one peptide = 0.52%). Blank = 0%, no peptide in the group. Rows are alphabetical; the chip beside each label is its chemical class.

This is composition, NOT enrichment — a residue frequent here may be just as frequent among the substrates. This is the background panel: the same matrix, on the same colour scale, for the controls. Compare with Figure 18 / 19 for positions 4–12 for the other group, and with Figures 16–17 for significance.

This panel is the N-terminal window only — positions 4–12, out to the 12th amino acid of the 24-mer — on the same 0–45% scale as the full 4–24 version, so the two are read the same way.
