

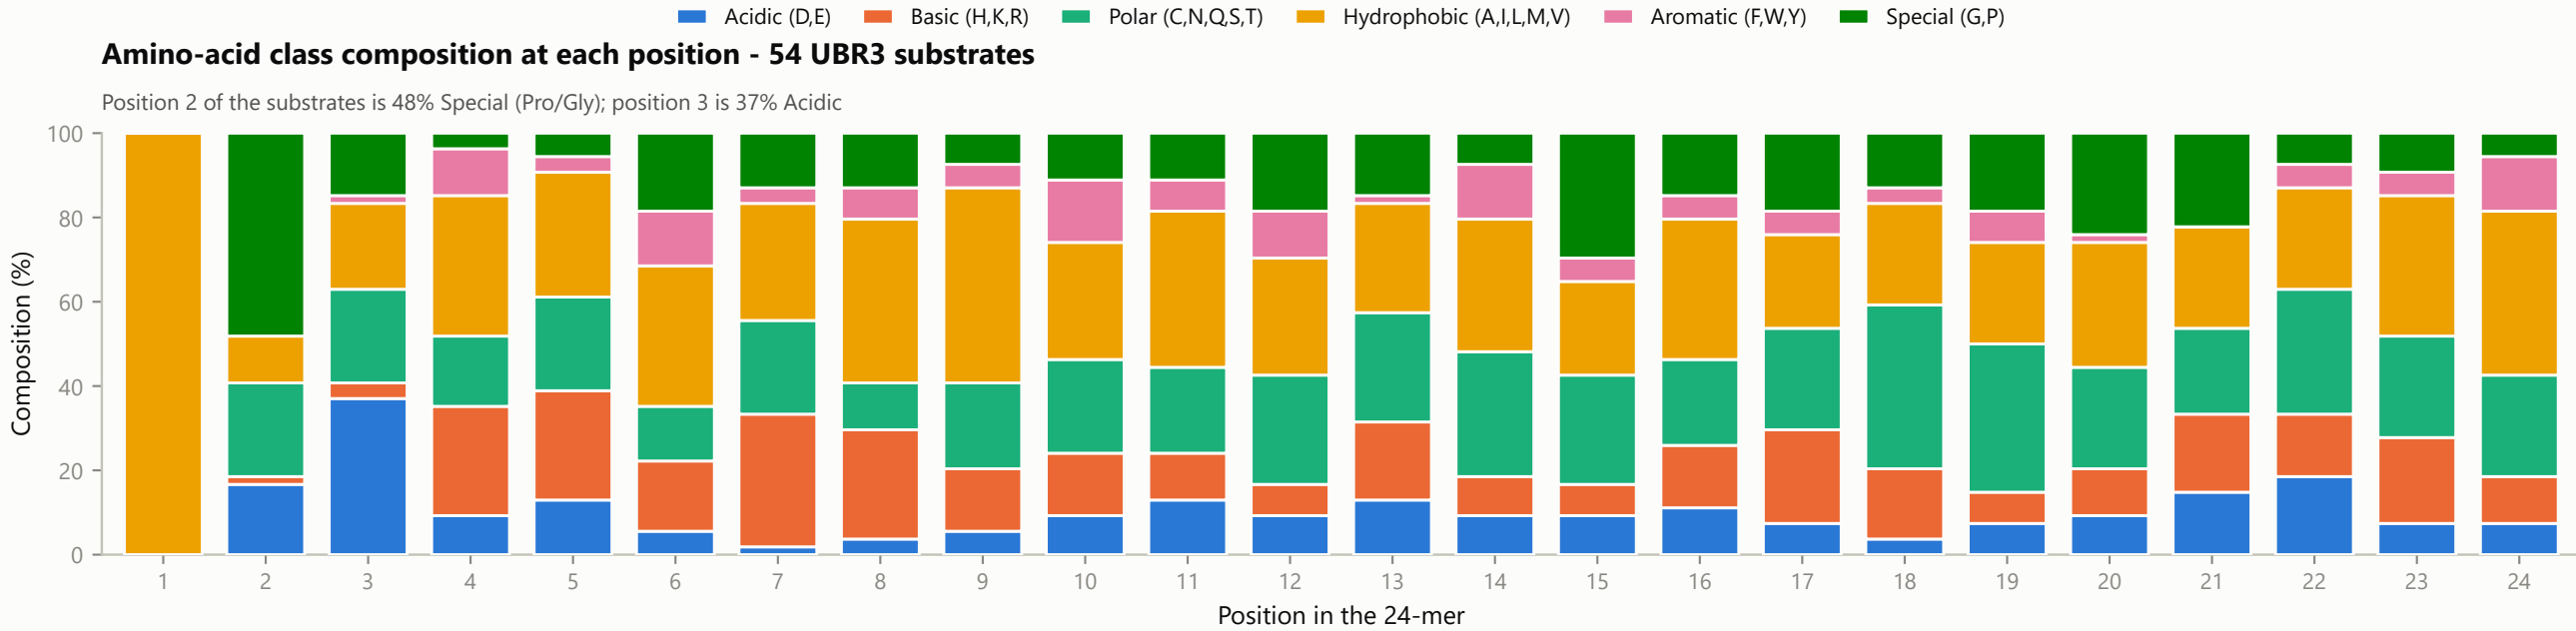

Figure 4 | Chemical-class architecture of the substrate N-termini across all 24 positions

Every residue of every peptide is assigned to one of six chemical classes. Only positions 2, 3 and 7 differ from the library after FDR correction.

A

Amino-acid class composition at each position - 54 UBR3 substrates

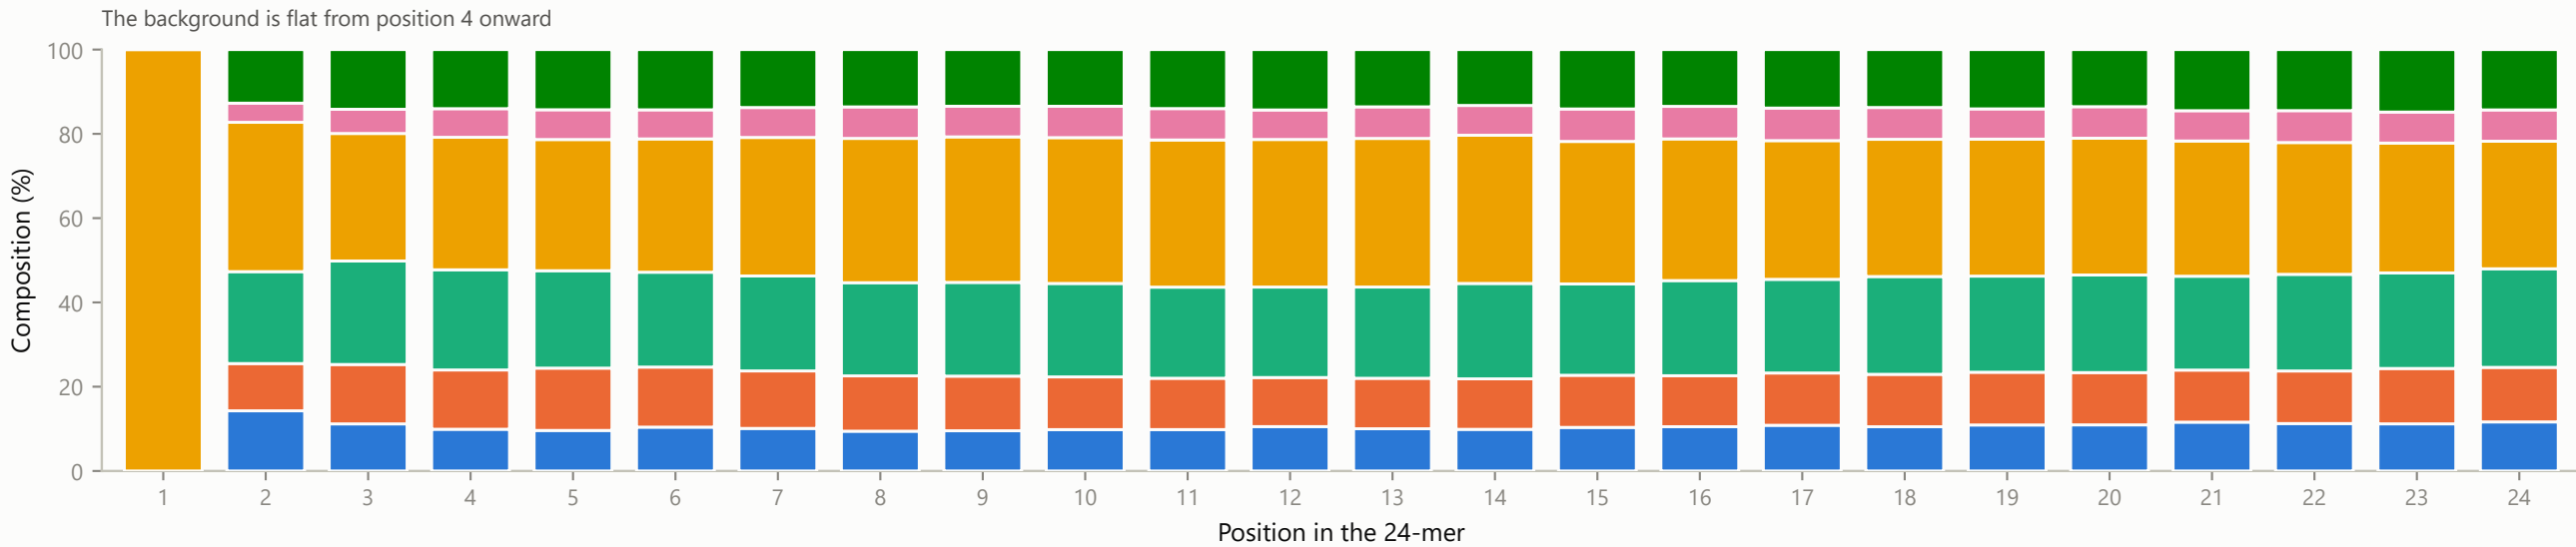

Position 2 of the substrates is 48% Special (Pro/Gly); position 3 is 37% Acidic

B

Amino-acid class composition at each position - 16,514 library peptides

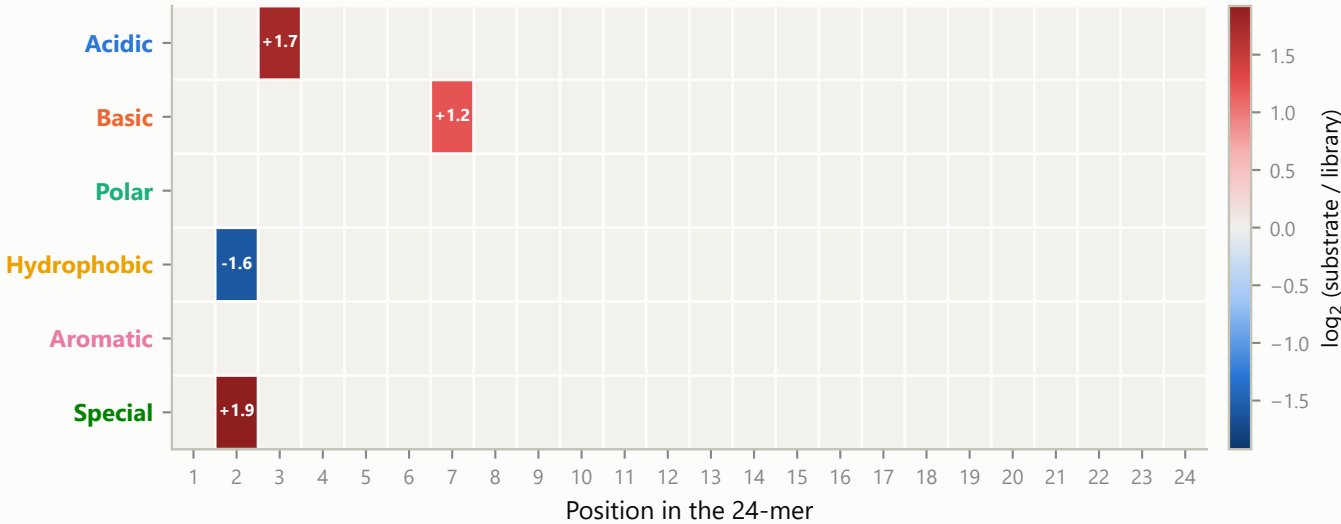

The background is flat from position 4 onward

C

Class enrichment by position (FDR-masked)

Beige = not significant at $q < 0.05$. Positions 2 and 3 dominate; Basic at position 7 is the only other survivor.

D

Whole-peptide composition is unchanged

Averaged over all 24 positions the substrates look like the library
