

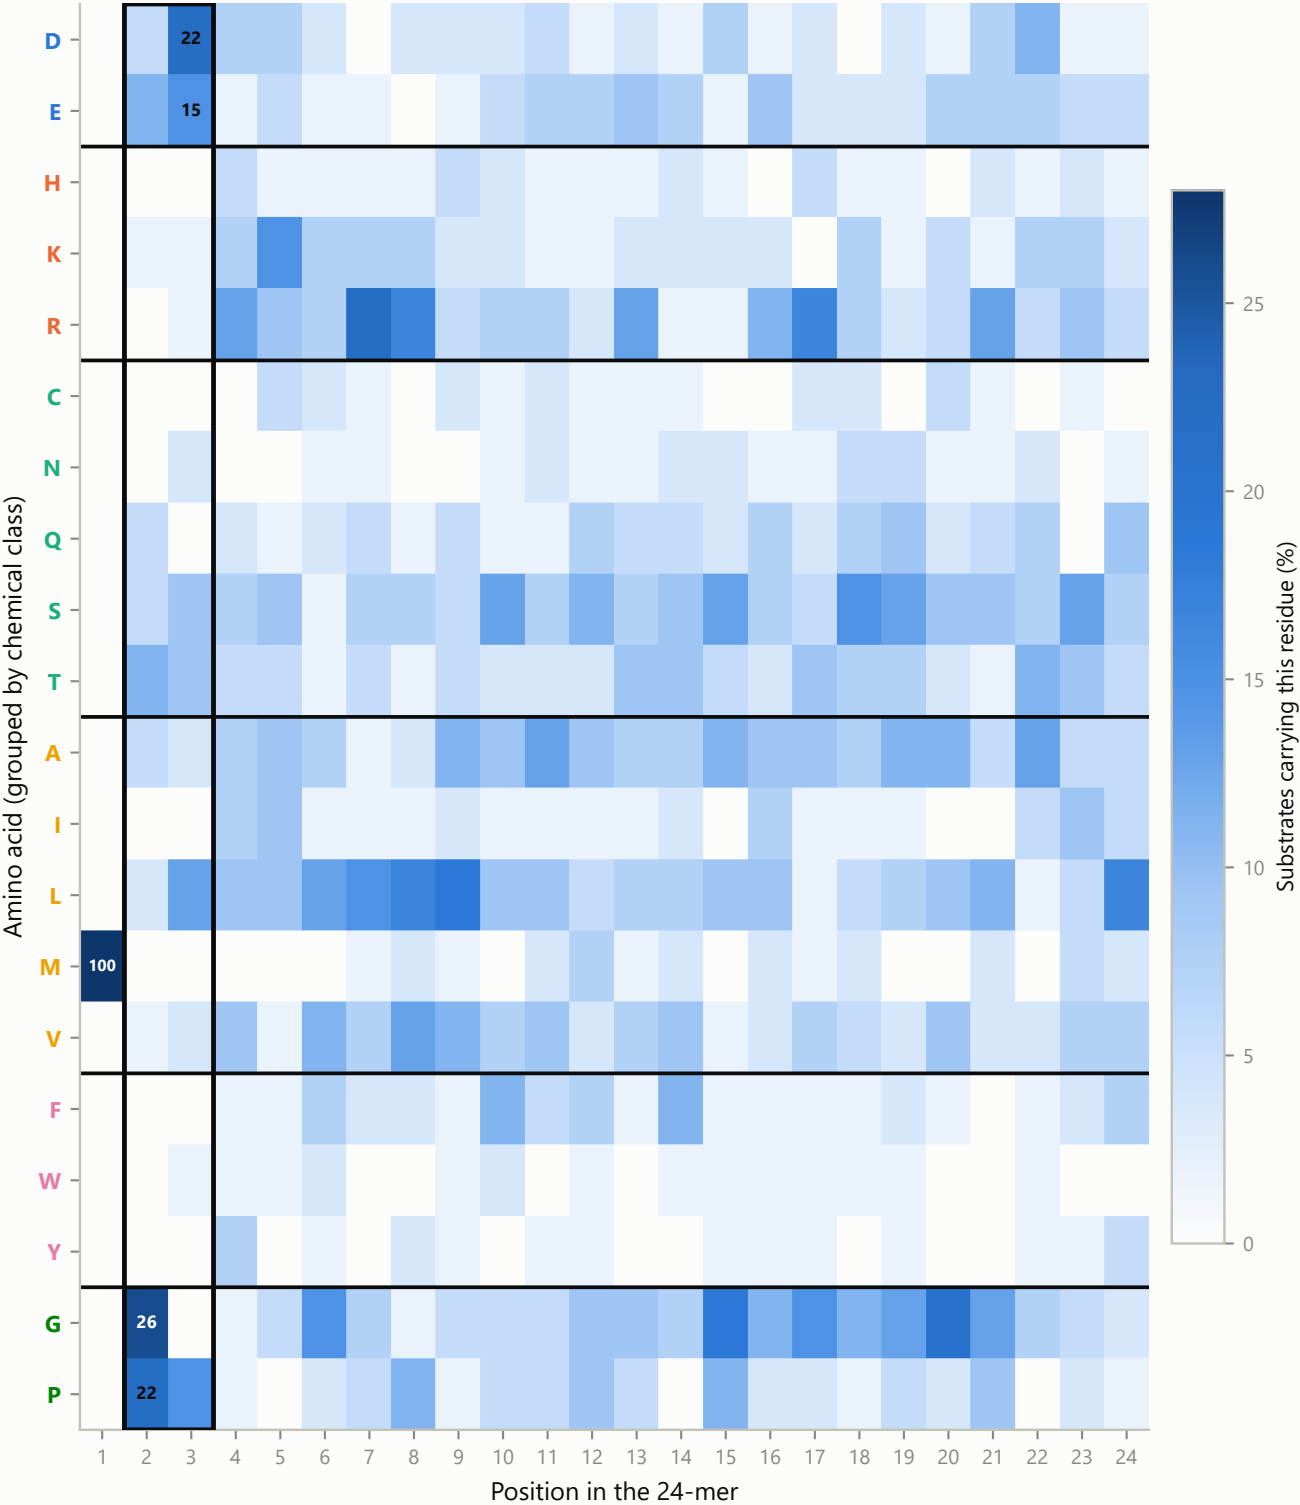

Figure 5 | Position-by-residue heatmaps of the 54 candidate UBR3 substrates

The dominant signal is a single block: Pro and Gly at position 2 and Asp at position 3. The only other cell surviving FDR is Arg at position 7 (22% of substrates vs 7% of the library).

A

Residue frequency in the 54 substrates

Boxed = positions 2-3. Met at position 1 is 100% (above the colour ceiling).

B

Enrichment over the library background (FDR-masked)

Beige = not significant. 4 of 480 position x residue cells survive $q < 0.05$: 3 at positions 2-3, plus Arg at position 7 ($q = 0.04$, borderline).
