

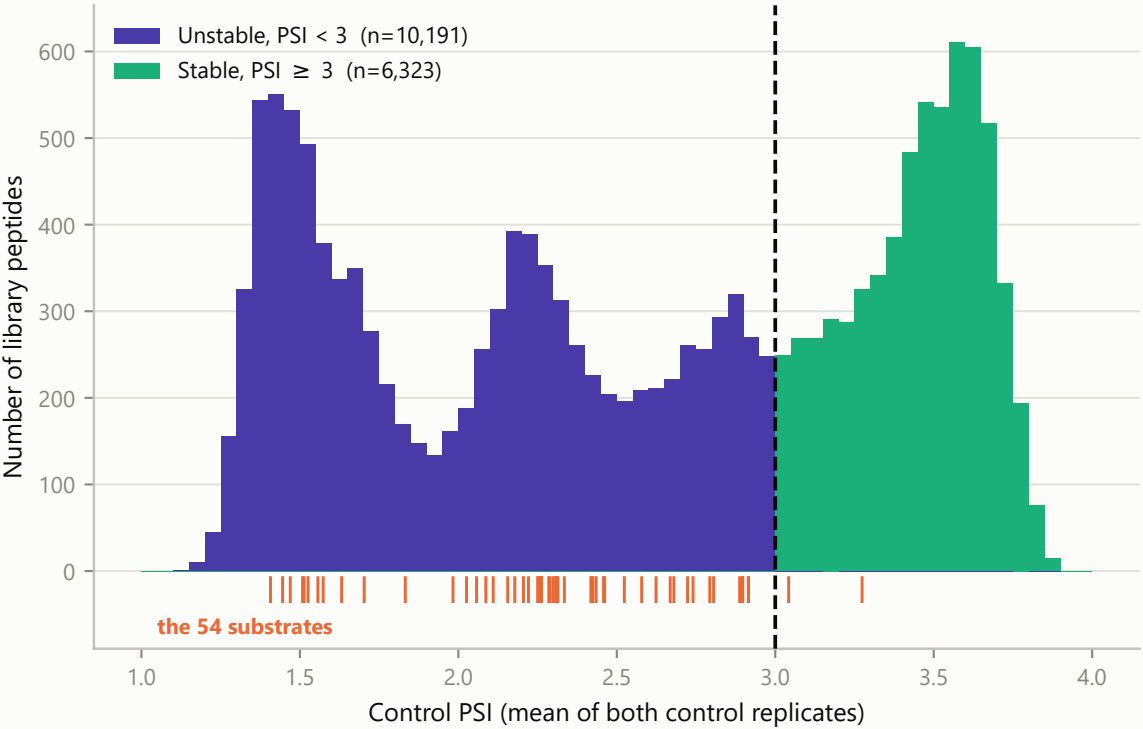

Figure 6 | Baseline stability: peptides above and below PSI 3

PSI is the read-weighted mean FACS bin (~1-4); PSI = 3 splits the library into unstable and already-stable halves. A degron substrate should start unstable and gain stability when its E3 ligase is lost - which is what the 54 substrates do.

A

62% of the library starts below PSI 3

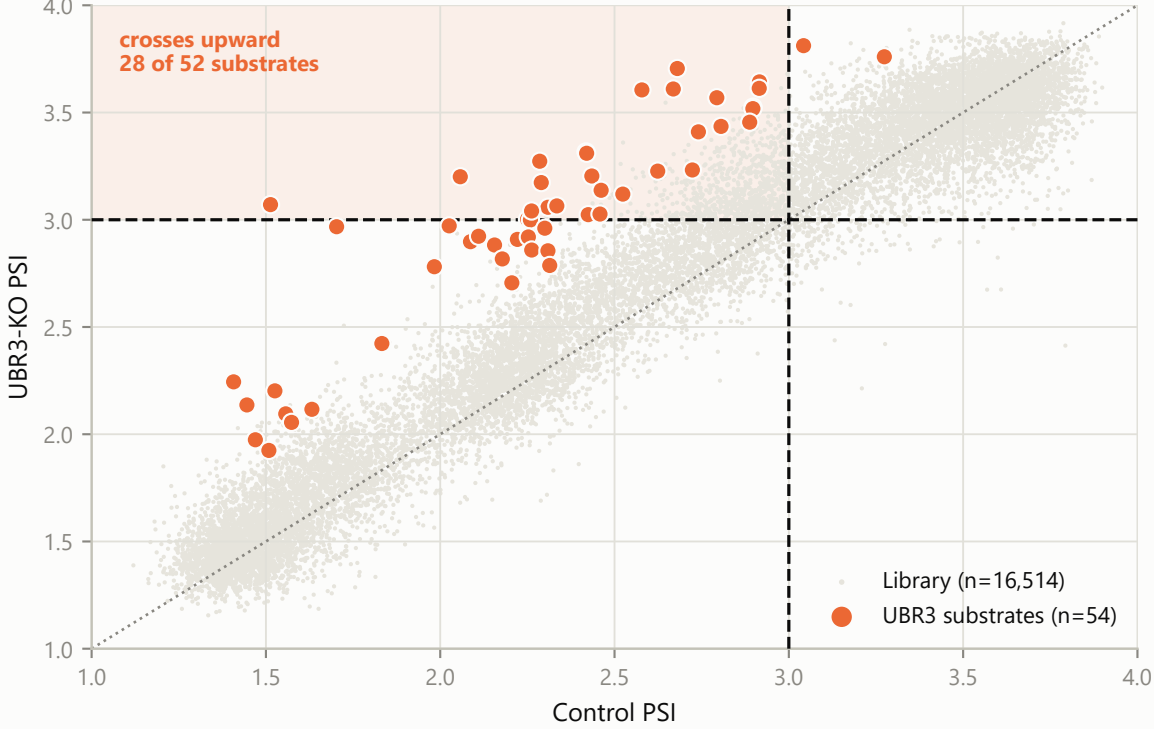

Ticks below the axis mark the 54 substrates - almost all sit in the unstable half

B

Over half the substrates cross the PSI 3 line

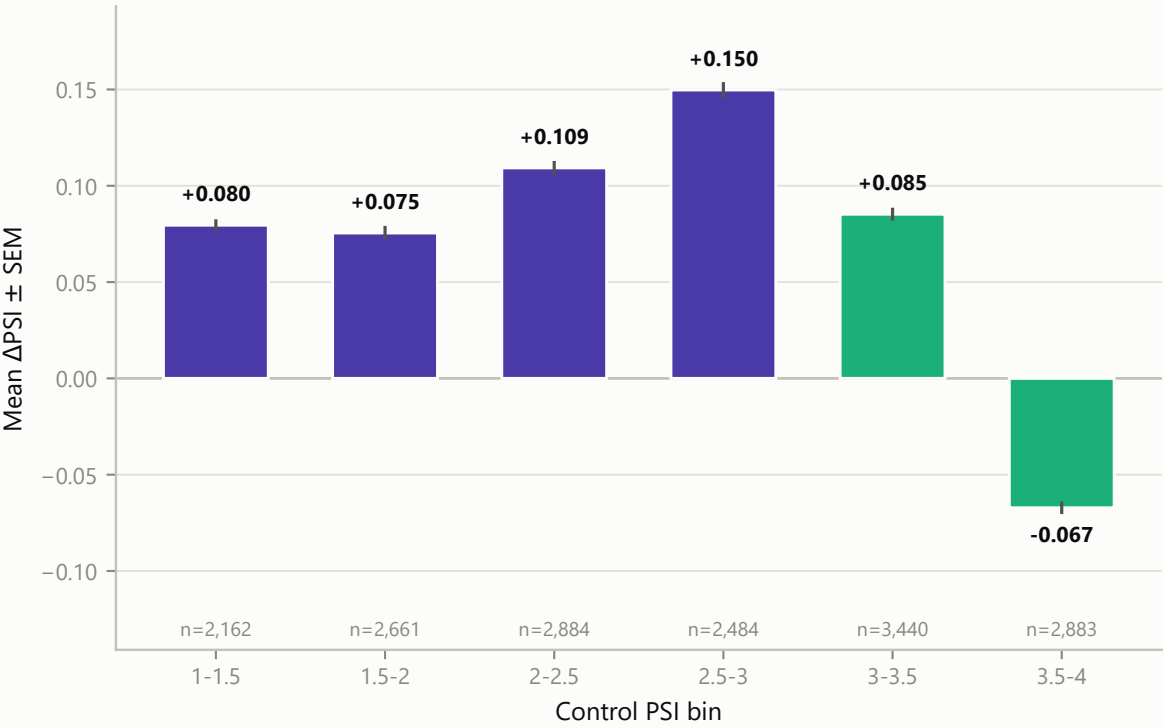

Dotted diagonal = no change. Shaded quadrant = unstable in control, stable in UBR3 KO.

C

Stabilisation saturates - and reverses - above PSI 3

Peptides that are already maximally stable have no headroom left to gain

D

Substrates are 16x more common below the line

Error bars are Wilson 95% confidence intervals; counts below each bar
