

Chemical class × position, coloured by significance

colour = $-\log_{10} p$, chi-square as reported in the workbook · Basic K H R · Acidic D E · Aromatic F Y W · Aliphatic G P A M · Hydrophobic V L I · Polar S T C N Q

n = 20 P/G-D/E/T substrates vs n = 193 non-substrate controls carrying the same motif.

Cell text is the fold change (substrates / controls) of every cell at p < 0.05, followed by the star bin of its uncorrected p: * p < 0.05, ** p < 0.01, *** p < 0.001.

No depleted cell reaches p < 0.05 anywhere in this dataset, so every coloured cell above is an enrichment. 5 of 126 testable cells reach p < 0.05 uncorrected, against 6 expected by chance alone — and only Basic at 8, Basic at 5, Basic at 7 survive BH-FDR across all 126 cells (q < 0.05) — the rest is not separable from that expectation.
