

Position × residue enrichment, coloured by SIGNIFICANCE (not fold change)

colour = $-\log_{10} p$, chi-square as reported in the workbook · deeper red = more significant

n = 20 P/G-D/E/T substrates vs n = 193 non-substrate controls carrying the same motif. Cell text is the fold change (substrates / controls) for cells at $p < 0.05$; * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$. Black outline = survives BH-FDR across all 416 cells ($q < 0.05$). Grey = residue absent from both groups, no test possible. No depleted cell reaches $p < 0.05$ anywhere in this dataset, so every coloured cell above is an enrichment. 25 of 416 testable cells reach $p < 0.05$ uncorrected, against 21 expected by chance alone — only the outlined cells are more than a multiple-testing artefact.
