

n = 20 P/G-D/E/T substrates vs n = 193 non-substrate controls. Heights are uncorrected p: 9 of the 179 cells shown reach p < 0.05 against 9 expected by chance, and none survives BH-FDR. This is the N-terminal window only — positions 3–11, out to the 11th amino acid; q is still BH-FDR across all 416 cells of the full 3–23 matrix.
