

n = 20 P/G-D/E/T substrates vs n = 193 non-substrate controls carrying the same motif.
Cell text is the fold change (substrates / controls) of every cell at p < 0.05, under the star bin of its uncorrected p: * p < 0.05, ** p < 0.01, *** p < 0.001.
No depleted cell reaches p < 0.05 anywhere in this dataset, so every coloured cell above is an enrichment. 4 of the 126 testable cells reach p < 0.05 uncorrected, against 6 expected by chance alone — and only Basic at 7 survives BH-FDR (q < 0.05) — the rest is not separable from that expectation.
