

n = 20 P/G-D/E/T substrates vs n = 193 non-substrate controls carrying the same motif. Rows are ordered by chemical class — Basic K H R · Acidic D E · Aromatic F Y W · Aliphatic G P A M · Hydrophobic V L I · Polar S T C N Q.
Cell text is the fold change (substrates / controls) of every cell at p < 0.05, under the star bin of its uncorrected p: * p < 0.05, ** p < 0.01, *** p < 0.001. Grey = residue absent from both groups, no test possible.
No depleted cell reaches p < 0.05 anywhere in this dataset, so every coloured cell above is an enrichment. 18 of the 416 testable cells reach p < 0.05 uncorrected, against 21 expected by chance alone — and none survives FDR correction, so no single cell here is more than a multiple-testing artefact.
